

OVER-THE-ROAD COSTS OF HAULING BULK MILK

341

ECONOMIC RESEARCH SERVICE
U.S. DEPARTMENT OF AGRICULTURE

ABSTRACT

This report uses synthetic cost analysis to develop total costs for a bulk milk transport carrying a 47,300-pound payload. Total trip costs are analyzed on the basis of mileage hauled, hundredweight, and hundred-weight trip mile. Results indicate cost per hundredweight trip mile is much greater for short-haul trips than for longer trips.

Keywords: Milk hauling costs, Bulk milk transport, Trucking costs.

SUMMARY

The cost of hauling bulk milk, as derived by synthetic cost analysis for a 47,300-pound payload, is much greater for short-haul trips--under 100 miles --than for longer trips. Beyond 100 miles, average total costs tend to be relatively constant on a per trip mile basis. Average total cost per hundred-weight trip mile was 0.161 cent at 100 miles, 0.139 cent at 275 miles, 0.13⁴ cent at 475 miles, and 0.129 cent at 650 miles. Subsistence costs for lay-over periods resulted in breaks in the total cost curve after 225, 450, and 675 miles.

Ownership costs allocated on a per trip basis, plus labor costs allocated on an hourly basis, plus operational costs distributed on a mileage basis, yielded total costs per trip. Total trip costs were analyzed on the basis of (1) hundredweight and (2) hundredweight per trip mile. Also, average total costs were broken down on the basis of estimated ownership, labor and operational costs plus subsistence costs per hundredweight per loaded one-way mile.

A step-by-step procedure is provided to assist managers and other interested persons in comparing their hauling costs with the estimates in this report. Assumptions and cost allocations can be varied to meet the needs of the individual operation.

OVER-THE-ROAD COSTS OF HAULING BULK MILK

INTRODUCTION

Significant changes in milk hauling and management practices have occurred in the past 4 years. These include shortening time periods used to depreciate transport equipment and eliminating two-driver operations in an attempt to reduce costs for long-distance hauls. Milk haulers are also using larger capacity semitrailer tank units for both farm pickup and over-the-road hauling. In some instances, haulers now are paying drivers a flat rate or amount per trip instead of an hourly or mileage rate.

This report deals with the cost of transporting bulk milk over relatively long distances. It revises the bulk milk transportation cost section of Marketing Research Report No. 791, Costs of Transporting Bulk and Packaged Milk by Truck, Economic Research Service, U.S. Department of Agriculture, May 1967.

Generally, the methodology used in the earlier report was followed in this report. Differences in the data and in some underlying assumptions reflect changes in milk hauling practices which have occurred in the interim period (appendix tables 14 and 15).

The building-block or synthetic approach was used to develop over-the-road hauling costs. These costs are not those incurred by a specific hauling operation or milk transport company but are estimated costs associated with various mileages for a given size payload. Assumptions and costs used in this report are based upon information obtained in discussions with milk haulers, an equipment dealer, and trade association representatives, and from examination of labor contracts applicable to milk transport drivers.

DEVELOPMENT OF COSTS

Truck Utilization Time

Truck utilization time was based on the assumption that one bulk milk transport unit would be available for duty 8,760 hours per year (365 days x 24 hours) for trips of various distances. Table 1 shows the estimated

average time required per trip to perform various functions. Certain operations, such as driver checkout and vehicle inspection, loading and unloading, washing and cleaning the tank unit, and waiting time, are associated with each haul regardless of distance. Driving time, on the other hand, varies with transport speed and distance traveled.

Loading and unloading times are those required at the sending and receiving plants for interplant shipments and not shipments between an assembly point and a processing plant. Waiting time includes only the period a transport unit and driver would have to wait to begin loading or unloading at a plant.

Tank washing and cleaning time reflects the use of clean-in-place equipment at the receiving plant. Layover time for a one-driver operation is based upon safety regulations which require a driver to have 8 hours off duty after 10 hours' driving time or 15 hours on duty.^{1/} Thus, 8 hours were added to the truck utilization time for each required layover.

Idle time is a residual figure representing the balance of time in a 24-, 48-, 72-, and 96-hour period not directly applicable to one of the specified functions. Maintenance time is included in this figure. Time required for vehicle maintenance is not directly associated with each individual trip but is based on accumulated miles. The cost of this operation is included as an operational (variable) cost which is allocated on the basis of miles traveled and not on the amount of time for each trip.

Ownership (Fixed) Costs

Ownership or fixed costs consist of depreciation (transport unit, building, and tools), insurance, interest, Federal highway use tax, State license and miscellaneous taxes, and administrative costs. The latter category includes management and office salaries, office supplies, utility expenses, legal fees, and miscellaneous office expenses (table 2).

Depreciation costs for transportation equipment were based upon information supplied by haulers. The depreciation cost per tractor unit and semitrailer tank unit was obtained by dividing the total depreciation expense charged off in 1969 for each type of equipment by the total number of units owned by the haulers in the study. This method reflects the varied depreciation methods--straight-line, declining-balance, or sum-of-the-years-digits--that can be or are used by individual haulers.

Milk haulers indicated a new tandem tractor would cost \$20,000 in 1969 and a new semitrailer tank unit, \$15,000. The tractor was estimated to have a useful life of 5 years and a salvage value of \$2,200; the semitrailer tank

Total ownership costs.....	10,879

1/ Maintenance shop and office space.

2/ Based on hauler data.

3/ Rate of 8 percent on midlife value of transport equipment.

4/ Department of the Treasury, IRS publication 349, Vehicle Class M, May 1969.

5/ Includes management and office salaries, office supplies, utility expenses, legal fees, and miscellaneous office expenses.

Building depreciation was based on a structure with the following specifications: private industrial garage used for trucking operations, 65 feet deep by 80 feet wide, concrete block and open-web steel truss construction, estimated useful life of 33 years, and replacement construction cost in 1969 of \$69,000.

Investment in tools was assumed to be \$5,000 with replacements being made to maintain a constant tool inventory figure. These tools include lubricating equipment, hoists, and specialty items required for operating a fleet of trucks and are considered to have a useful life of 10 years. Individual mechanic's tools are not included in the tool depreciation figure.

Interest charges were based only on the midlife value of the milk transport unit and computed at the rate of 8 percent. Insurance, State licenses, and miscellaneous taxes were synthesized from information obtained from milk haulers and trade associations. Costs for management and office salaries, office supplies, utility expenses, legal fees, and miscellaneous office expenses included under the administrative cost category were based on information supplied by milk haulers.

Labor Costs

Labor was considered a separate cost category rather than a component of operating (variable) costs. This was done to account for payments to the driver for driving time and for time required during a trip when he was not actually driving the transport but was still on duty. A transport driver may receive one basic hourly rate of pay for actual driving time and another for waiting, loading and unloading, or other nondriving on-duty time. However, to facilitate allocation of costs in this report the same hourly wage rate was assumed for all on-duty time, including not only the time the operator was driving the transport but also any other time the transport was standing idle when the driver's presence was required.

Standard hours per workweek vary widely in the milk hauling industry. Haulers operate on the basis of a 5-, 6-, or 7-day workweek. Therefore, it was assumed that overtime wages would not be paid until a driver had worked 40 hours. Overtime costs are not included as it was assumed management would schedule hauling operations to avoid payment of overtime wages.

Labor costs consist of the driver's basic wage plus fringe benefit payments. These fringe payments include pension, health and welfare contributions, vacation, paid holidays, social security (employer's share only), unemployment compensation insurance, and workmen's compensation insurance (table 3).

Table 3.--Labor cost per on-duty hour, bulk milk transport unit, 1969

Item	Cost per on-duty hour
Average basic wage 1/.....	Dollars 3.429
Pension 2/.....	.226
Health and welfare 2/.....	.194
Vacation 3/.....	.158
Paid holidays 3/.....	.093
Social security 4/.....	.162
Unemployment compensation insurance 5/..	.006
Workmen's compensation insurance 6/....	.123
Total labor cost per on-duty hour..	4.391

1/ Based on hauler and labor contract data.

2/ Based on 40-hour workweek per driver.

3/ Based on 2 weeks' vacation, 6 paid holidays, and 49-week work year per driver.

4/ Based on 1969 Federal tax rate of 4.87 percent per first \$6600 annual earnings.

5/ Assumes employer complies with State law and receives a 90-percent reduction from 3.1-percent Federal tax rate for a 0.4-percent rate per first \$3000 earnings.

6/ Based on data furnished by National Council on Compensation Insurance.

The basic hourly wage rate was based on hauler and labor contract rates. All other labor payments were converted from a monthly or annual figure to a weekly equivalent and then divided by the standard workweek of 40 hours to obtain an hourly cost figure.

Operational (Variable) Costs

Operational costs, that is, variable costs, were developed on a mileage basis for a bulk milk transport unit having a rated tank capacity of 5,500 gallons or a 47,300-pound payload. These costs consist of fuel, tires, maintenance (including oil, grease, and parts and labor for repairs), and miscellaneous items such as road tolls, weighing fees, and other transportation expenses directly related to the over-the-road operation of the transport unit (table 4). These figures were also converted to dollars per driving hour.

Basic data for all operational cost items were obtained in discussions with bulk milk haulers. Diesel fuel costs include the applicable Federal, State, and local taxes. Table 5 shows the average cost per tire per operational mile. Variations reported in tire wear and the number of times a carcass was recapped were due to varying road conditions and operating practices existing among haulers.

Table 4.--Operational (variable) costs for operating a bulk milk transport unit, 47,300-pound payload, 1969

Item	Cost per mile	Cost per driving hour <u>1/</u>
	Cents	Dollars

Cost per transport unit per mile (18 tires):	Cents	1.87

1/ Assumes new tube purchased each time new tire purchased.

2/ Based on two recaps per new tire casing.

Subsistence Costs

A subsistence allowance of \$9 a night to compensate the transport driver for overnight lodging and eating expenses was added to the variable operational costs to obtain the total trip cost where applicable. These costs amounted to an additional \$9 for round trips between 451 and 900 miles, \$18 for trips between 900 and 1300 miles, and \$27 for trips of 1400 and 1500 miles. This allocation was based on the driving limitation of 10 consecutive hours established by the Department of Transportation Safety Regulations.

RESULTS OF ANALYSIS

Average Costs

Estimated average ownership, labor, operational plus subsistence, and total costs were calculated for a 7-day week hauling operation using a 47,300-pound payload transport unit and one driver (table 6).

Ownership or fixed costs were allocated on the basis of the estimated total number of trips that might be made for specified hauling distances in a year. These costs are incurred each hour of the year whether the transport is hauling milk, being repaired, or standing idle. When allocated on an hourly basis over the total number of hours in a year ($365 \times 24 = 8,760$ hours), fixed cost per hour would be the same whether the hauler was operating on the basis of a 5-, 6-, or 7-day week.

1/ Assumes transport unit returns empty on backhaul. Doubling each mileage figure equals the round-trip mileage used in table 1.

2/ Sum of individual items may not equal total shown due to rounding of individual items.

Ownership costs can only be recovered when the transport is actually hauling milk. When these costs are distributed over the estimated number of trips of specified mileage that might be made in a year, they increase as the working days in the week are reduced. This method of allocating fixed costs appears to be more realistic than using an hourly basis. It accounts for variations in the normal workweek of haulers as well as for differences resulting from slack and peak seasons of milk production and shipping. Labor costs were handled on an hourly rate basis and also as a separate cost category. Operational and subsistence costs were combined into a single cost and allocated on the basis of the distance per trip.

Estimated average ownership, labor, operational plus subsistence, and total costs were also developed for 5- and 6-day week operations. In these instances, all costs except ownership were identical to those for the 7-day week. Ownership (fixed) costs were slightly higher, because they were allocated over fewer trips for the specified mileages. Labor and operational plus subsistence costs were allocated over the identical mileages used for the 7-day week analysis. Thus, these cost estimates would remain unchanged. A comparison of ownership costs is presented in table 7.

Figure 1 shows the effect of hauling distances on the average total, fixed, labor, and variable plus subsistence costs for a 7-day week bulk milk hauling operation. Since the average cost curves for a 5- and 6-day week operation would follow the same general pattern, only the 7-day period is shown.

Average Costs: 25-100 Mile One-Way Haul

Generally, as distances increase, average total costs per hundredweight trip mile decrease. This results primarily from declines in fixed and labor costs associated with increased mileage, whereas variable and subsistence costs remain relatively stable. These latter costs, however, tend to represent a greater proportion of the total average cost after 225, 450, and 675 miles when subsistence costs, paid to the transport driver for an overnight or 8-hour layover period after 10 hours of driving, are added.

The sharpest decrease in ownership or fixed and labor costs occurs for hauls ranging between 25 and 100 miles. For example, fixed and labor costs for a 25-mile haul average 0.074 and 0.163 cent per hundredweight trip mile, respectively. At 100 miles, these costs are 0.032 and 0.072 cent. Overall, these differences represent decreases per loaded trip mile of 58 percent in fixed costs and 62 percent in labor costs. These drops reflect the fairly rapid decline in fixed and labor costs as hauling distances are increased beyond the 25 mile figure. At the same time, operational or variable costs remain unchanged at 0.056 cent per loaded trip mile.

Average total costs, as a result of the foregoing changes in fixed and labor costs, fell from 0.294 cent per hundredweight trip mile at 25 miles to 0.161 cent per hundredweight trip mile at 100 miles--a 45-percent drop.

1/ Assumes transport unit returns empty on backhaul. Doubling each mileage figure equals the round-trip mileage used in table 1.

2/ Based on Department of Transportation Safety Regulations which require 8 hours off-duty time after 15 hours' on-duty time or 10 hours' driving time.

**ESTIMATED AVERAGE COSTS OF TRANSPORTING BULK MILK,
47,300-POUND PAYLOAD, ONE DRIVER, 1969**
(7-Day Week Operation)

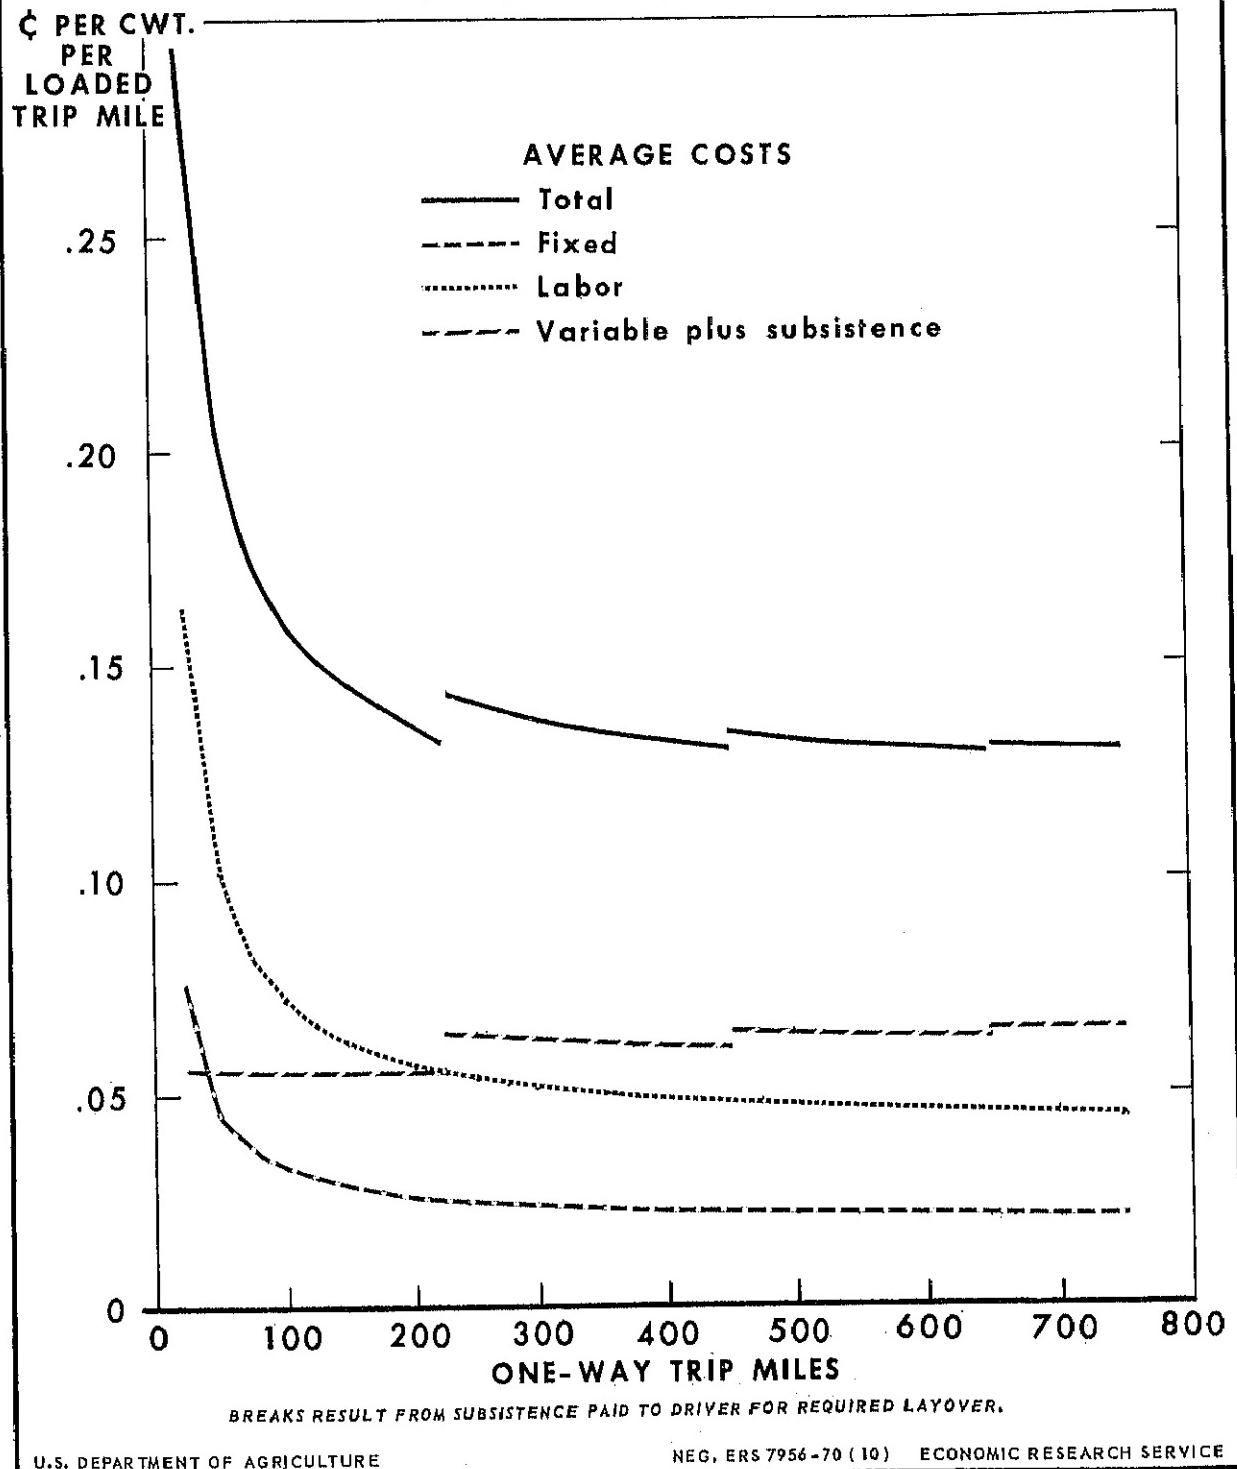

Figure 1

Average Costs: 100-400 Mile One-Way Haul

Fixed and labor costs decline at a much smaller rate for hauls exceeding 100 miles than for distances between 25 and 100 miles. On hauling distances between 100 and 400 miles, both fixed and labor costs decline slowly, while operational or variable costs remain constant at 0.056 cent per loaded one-way mile for all trip distances up to and including 225 miles. At this point, they increase to 0.064 cent, due to the addition of subsistence expenses, and then decline to 0.061 cent at the 400-mile hauling distance. In this instance, average total costs drop from 0.161 cent per hundredweight per one-way loaded trip mile for 100-mile hauling distances to 0.132 cent at 400 miles--an 18-percent drop.

Average Costs: 400-750 Mile One-Way Haul

On hauling distances between 400 and 750 miles, fixed and labor costs continue to average lower for each additional hauling mile. On the other hand, additional subsistence costs increase the total variable and subsistence cost from 0.061 to 0.064 cent per hundredweight per loaded one-way trip mile.

Despite increased variable and subsistence costs, average total costs declined from 0.132 to 0.130 cent per hundredweight loaded trip mile--a 1.5-percent decrease.

Total Costs

Estimated total cost figures were computed for a 5-, 6-, and 7-day week operation. As shown in table 8, these total costs were (1) per hundredweight and (2) per hundredweight mile.

The hundredweight costs per mile for the distances shown were used to develop a series of total cost functions for the transportation of bulk milk on a 7-day week basis (table 9). Cost functions for 5- and 6-day week operations follow patterns similar to that for 7 days. These equations relate hundredweight per mile costs to one-way mileage and assume no backhaul cargo was carried.

Figure 2 shows the effects of hauling distance on total costs of milk transport. Breaks occurring in the total cost curve after 225, 450, and 675 miles result from the subsistence paid to the transport operator for an overnight or 8-hour layover after 10 hours' driving time.

Table 8.—Estimated costs of transporting bulk milk over various distances by bulk milk transport,
47,300-pound payloaded, one driver, 5-, 6-, and 7-day week operations, 1969

	107						

1/ Assumes transport unit returns empty on backhaul. Doubling each mileage figure equals the round-trip mileage used in table 1.

2/ Based on Department of Transportation Safety Regulations requiring 8 hours' off-duty time after 15 hours' on duty or 10 hours' driving time.

Table 9.--Bulk milk transportation cost functions, tractor and semitrailer tank transport units, 47,300-pound payload, one driver, 7-day week operation, 1969

One-way mileage interval	Applicable equations
25-225	$Y = 4.434 + .058X$
226-450	$Y = 6.293 + .058X$
451-675	$Y = 8.878 + .058X$
676 plus	$Y = 8.444 + .059X$

Y = Cents per cwt.

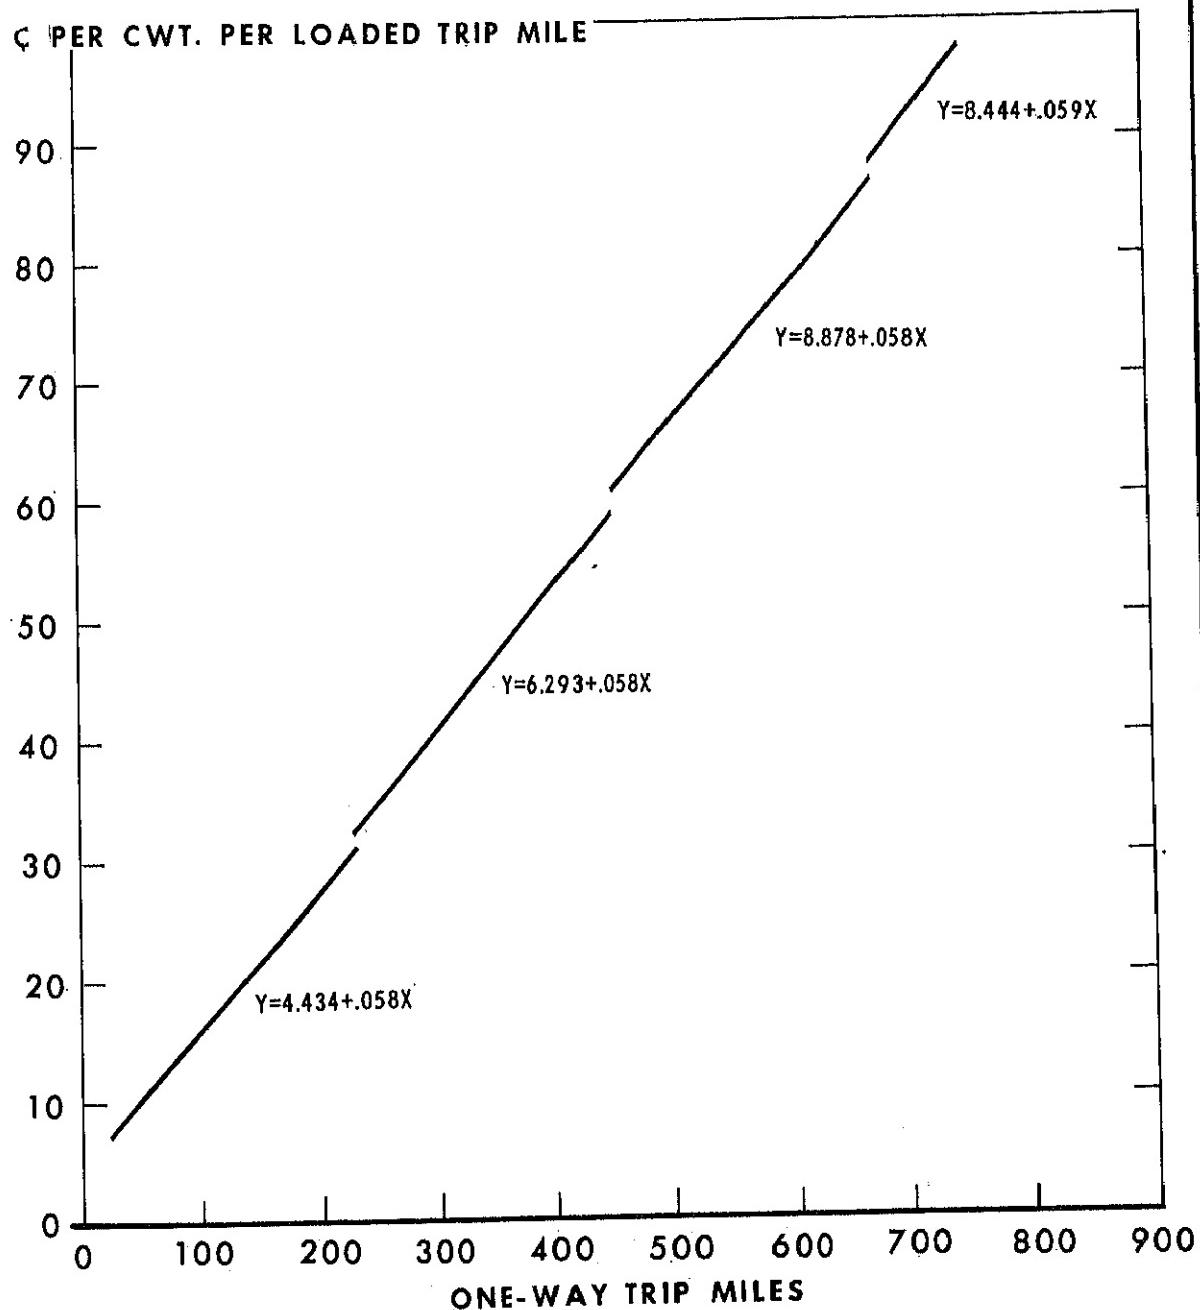

X = One-way trip mileage.

USE OF DATA

The preceding estimates can be used by milk haulers and other interested parties to compare their own operating data. These cost data are synthesized for a few specified conditions and assumptions; no effort has been made to cover the wide range of possible conditions under which haulers operate. By following the step-by-step procedures shown in tables 10-13 and making entries in the blank columns provided, a hauler can vary the assumptions and input specifications to coincide with his operations and make meaningful comparisons. This procedure also can be used to compare the effects on costs of various changes in transport equipment and hauling practices.

**TOTAL UNIT COST OF TRANSPORTING BULK MILK,
47,300-POUND PAYLOAD, ONE DRIVER, 1969**

(7-Day Week Operation)

BREAKS RESULT FROM SUBSISTENCE PAID TO DRIVER FOR REQUIRED LAYOVER.

1/ 1966 study average labor costs per mile multiplied by 40 m.p.h. to obtain comparable 1969 cost per on-duty or driving hour.

2/ 1966 data includes welfare payments.

3/ 1966 basic wage rate includes payment for vacation and paid holidays. Also, contract data used in 1966 were for general freight labor contracts and these rates were not directly applicable to bulk milk hauling. 1969 basic wage rates based on union contracts directly applicable to bulk milk hauling plus individual hauler data.
